

Blood Glucose Level

Blood glucose level is the measure of the amount of glucose present in a patient's blood. It is important for the body's function of producing energy and functioning of the vital organs. About 14% of the global adult population is affected with diabetes. Diabetes affects the body's function to produce insulin, which is essential in regulating blood glucose levels. A large sum of patients are unaware of their condition and do not receive treatment for diabetes. Also blood glucose level can affect patients of shock and altered mental statuses. The normal clinical range for blood glucose is measured to be about 70-140 mg/dL. 69 mg/dL readings and below are considered hypoglycemic and levels above 180 mg/dL are considered hyperglycemic. Hypoglycemic patients are at risk to life-threatening symptoms such as seizures, coma if left untreated immediately. During triaging, medical professionals can test blood glucose level to identify high risk patients of hypoglycemia. This level of blood glucose allows healthcare workers to administer the proper care to patients to prevent life threatening symptoms and also prevent hyperglycemic symptoms such as diabetic ketoacidosis (DKA). This measurement can often be overlooked but is usually the background to many medical problems
